HC mix®

phalaenopsis crop

In the first two months after potting the plants, it costs the phalaenopsis grower large effort to get the supply of nitrogen to a sufficient level. On the other hand the pH level during this stage is quite high. These two factors can cause an inferior growth of the phalaenopsis. Existing fertilizers does not offer the right solution to these problems. Horticoop has developed the **HC mix** together with the company “Slingerland Potgrond”. After many experiments with phalaenopsis growers, this special addition (HC mix) to the bark ensures optimum growth, also in the first months.

Especially the vegetative growth will be influenced. The assimilation of the plant will be better and therefore the colour of the plant will be significantly darker. Moreover the HC mix lowers the pH level. As a result of this the plant will better absorb the phosphate and will obtain a better root system.

For an optimal availability of nitrogen to the plant we advise to add 5 kg HC mix per m³ bark.
